

The landscape of expression and alternative splicing variation across human traits

Raquel Garcia-Perez
Juan de la Cierva postdoctoral researcher
Transcriptomics and functional genomics lab
Barcelona Supercomputing Center

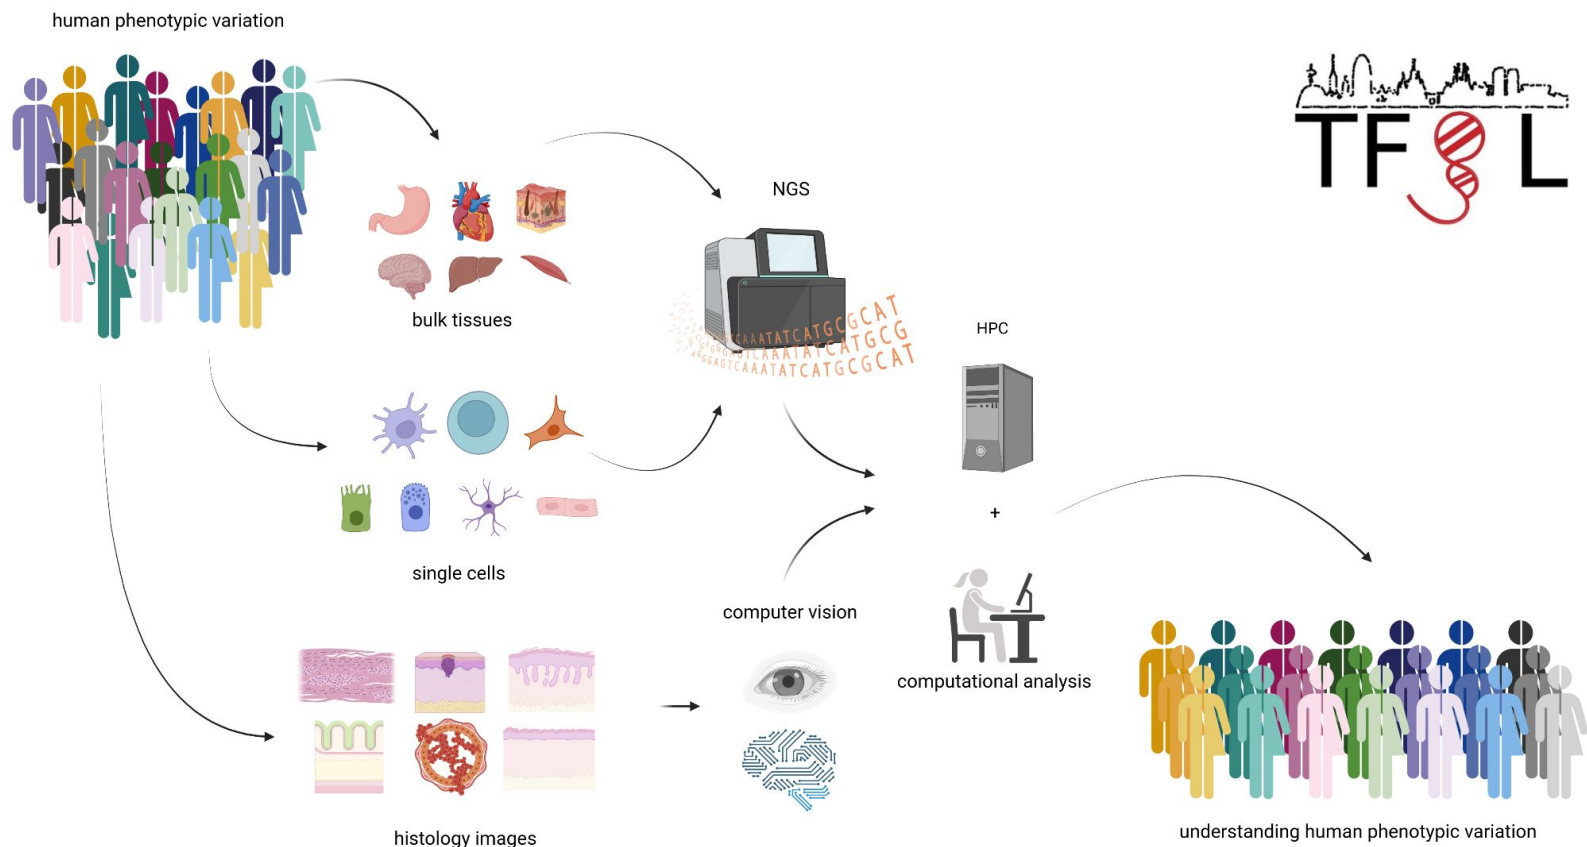

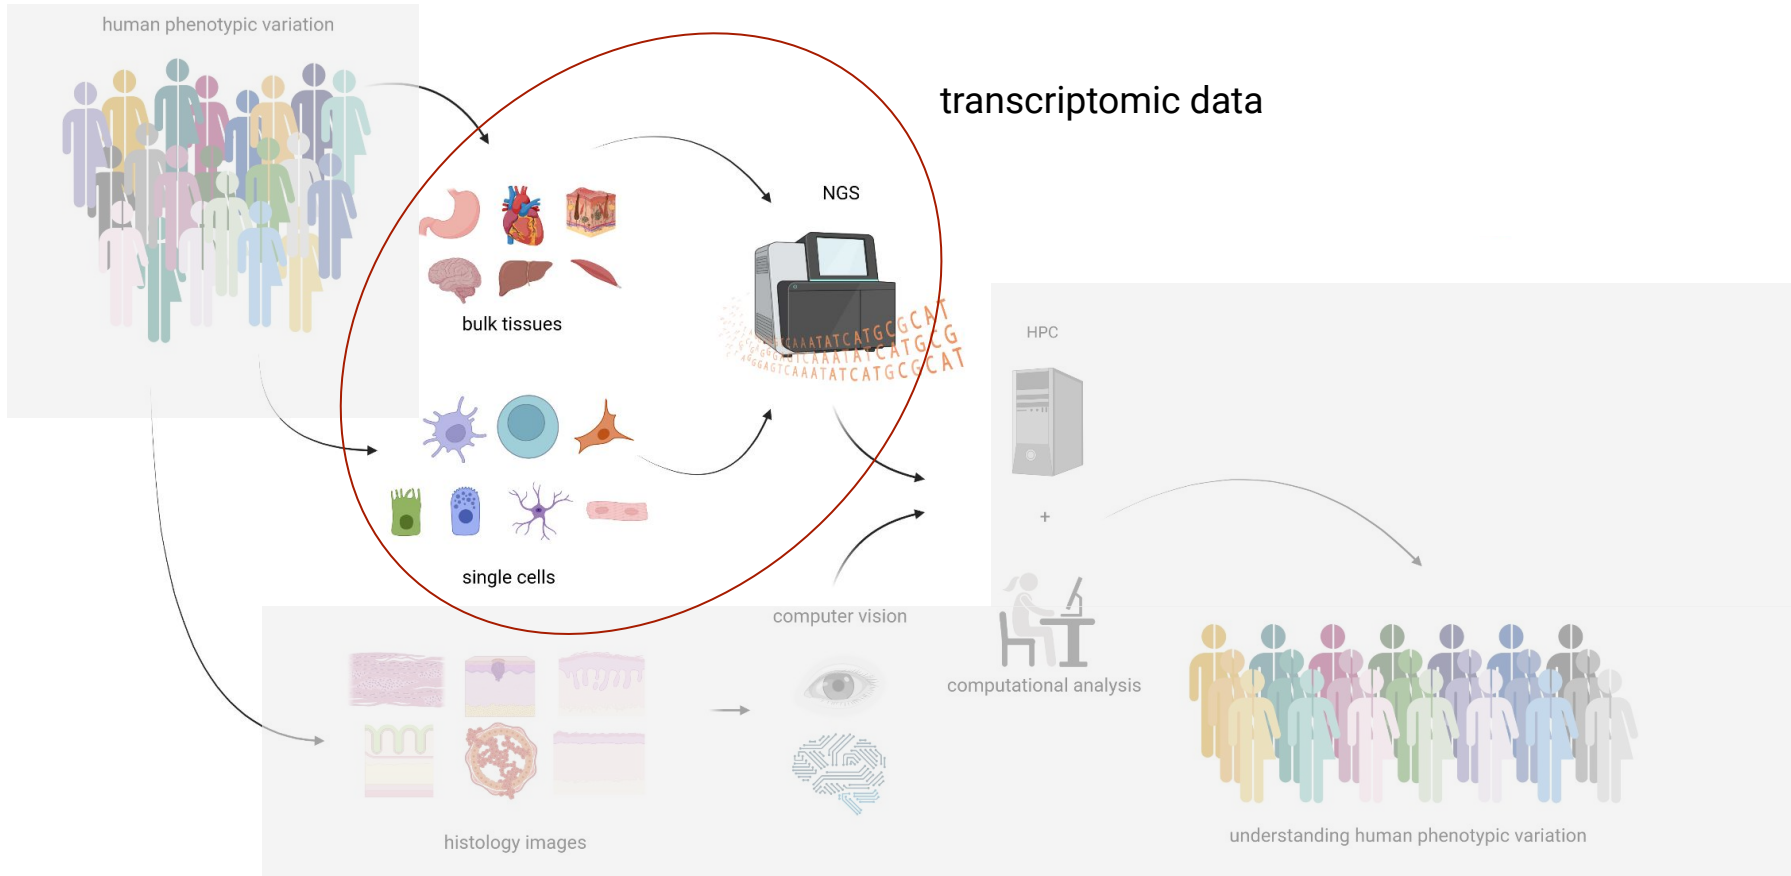

human phenotypic variation

understanding human phenotypic variation

From **gene expression** to human phenotypes

transcription

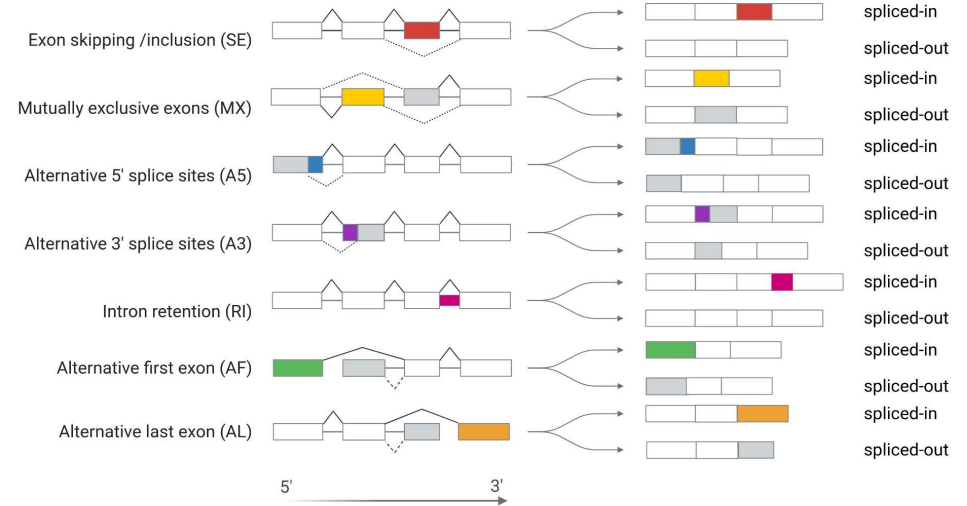

From **gene expression** to human phenotypes

From **gene expression** to human phenotypes

From **alternative splicing** to human phenotypes

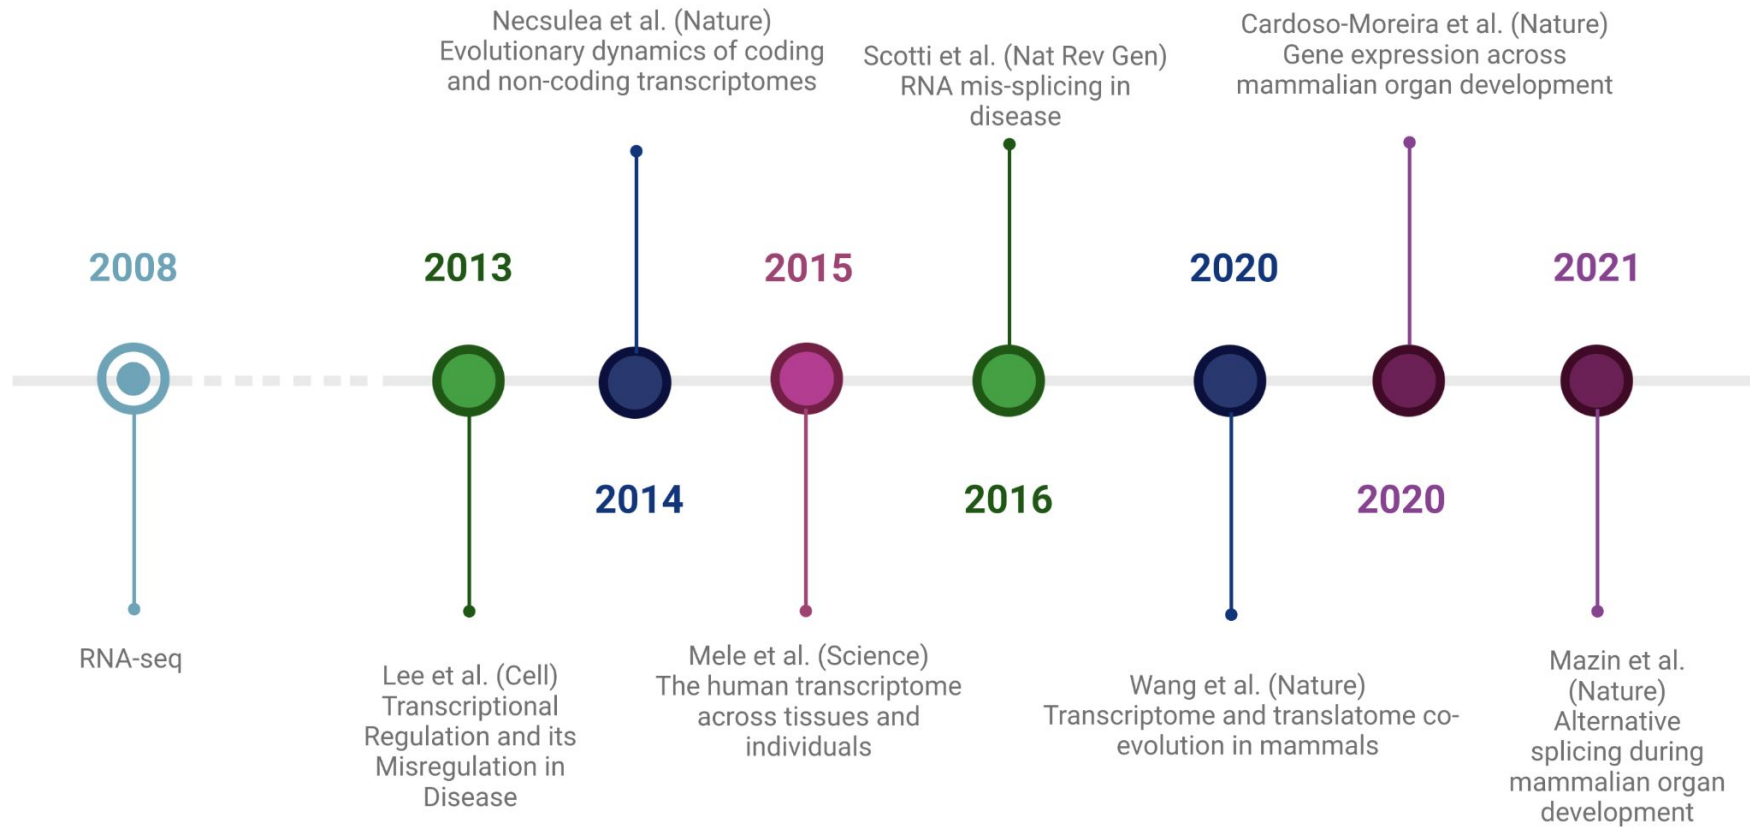

From **alternative splicing** to human phenotypes

From **alternative splicing** to human phenotypes

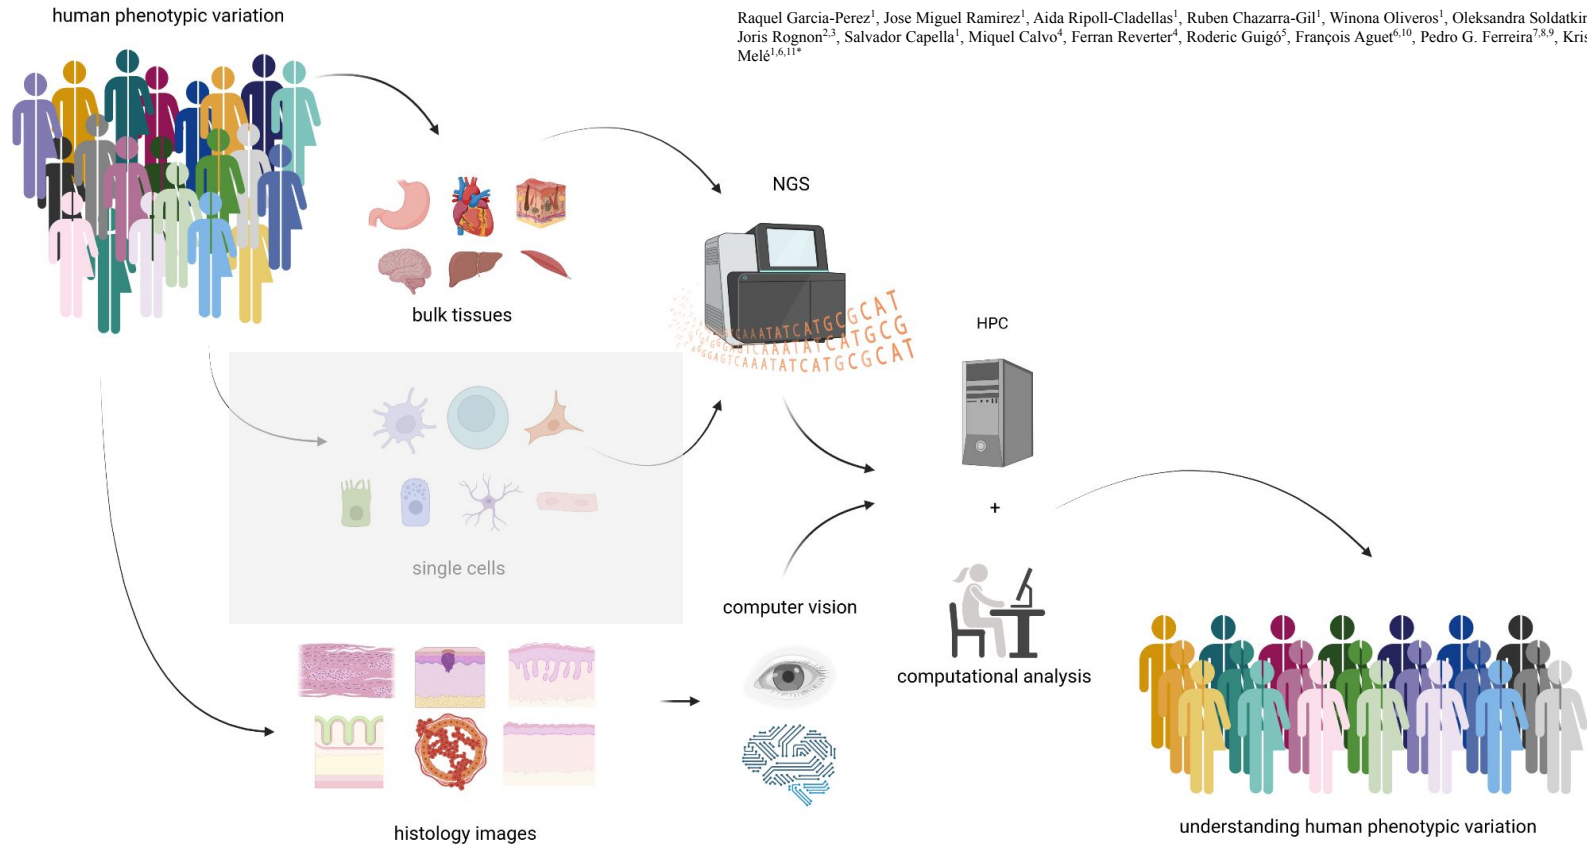

Lack of **multi-tissue** and **multi-trait** transcriptomic studies

- Transcriptomic studies limited to one or few tissues
- Transcriptomic studies limited to a single trait
- Transcriptomic studies limited to gene expression or alternative splicing

The landscape of expression and alternative splicing variation across human traits (under review)

Ferreira^{7,8,9}, Kristin G. Ardlie⁶ & Marta Melé^{1,6,11*}

The landscape of expression and alternative splicing variation across human traits (under review)

Raquel Garcia-Perez¹, Jose Miguel Ramirez¹, Aida Ripoll-Cladellas¹, Ruben Chazarra-Gil¹, Winona Oliveros¹, Oleksandra Soldatkina¹, Mattia Bosio¹, Paul Joris Rognon^{2,3}, Salvador Capella¹, Miquel Calvo⁴, Ferran Reverter⁴, Roderic Guigo⁵, François Aguet^{6,10}, Pedro G. Ferreira^{7,8,9}, Kristin G. Ardlie⁶ & Marta Melé^{1,6,11*}

GTEx v8 data

RNA-seq, WGS and
histology images

46 tissues
781 individuals

22,967 genes
62,269 splicing events

Demographic traits

Clinical traits

Tissue-specific contribution of human traits to gene expression variation

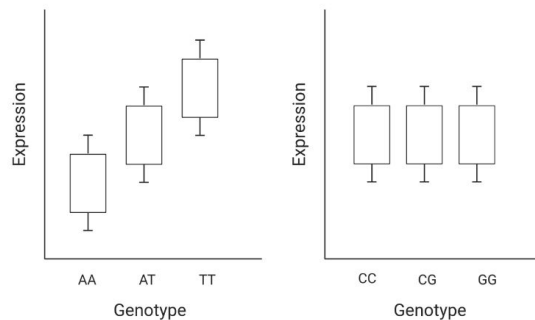

Tissue-specific contribution of human traits to gene expression variation

Tissue-specific contribution of human traits to gene expression variation

Gene expression and alternative splicing differences between human populations are under **genetic control**

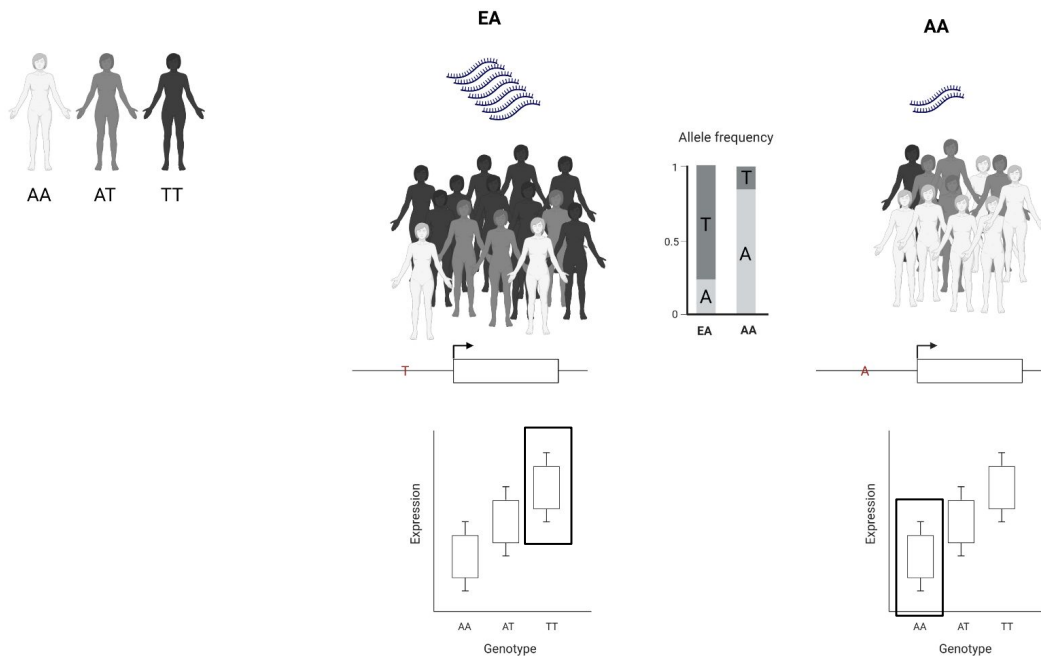

regulatory variation is measured as expression quantitative trait loci (eQTL)

regulatory variation is measured as splicing quantitative trait loci (sQTL)

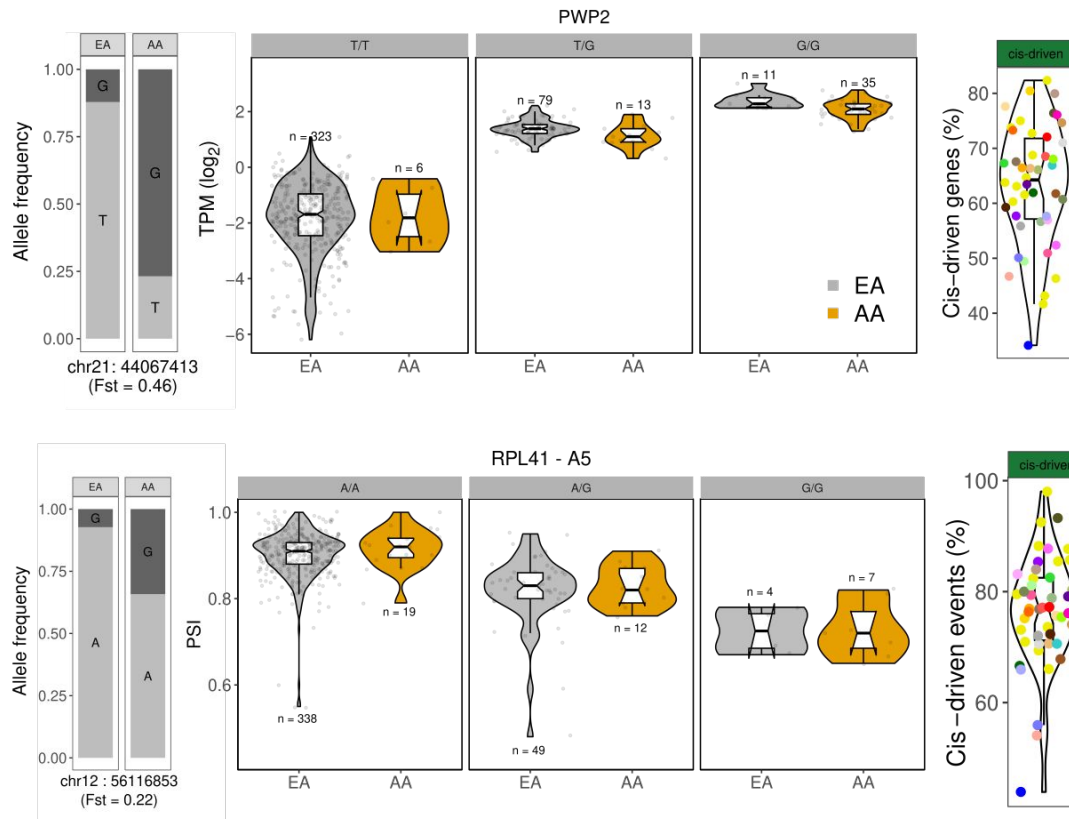

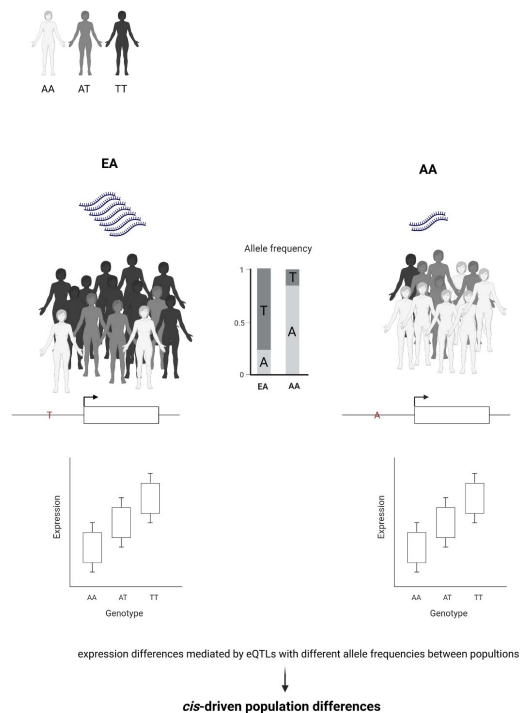

Gene expression and alternative splicing differences between human populations are under **genetic control**

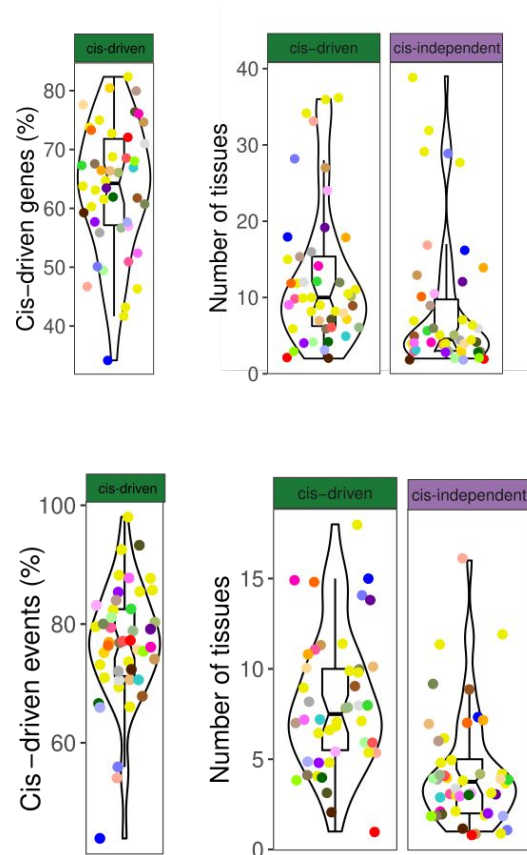

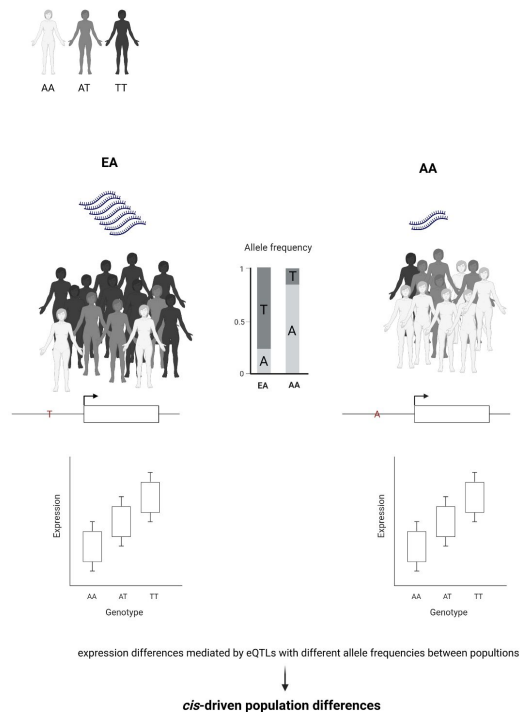

expression differences mediated by eQTLs with different allele frequencies between populations

***cis*-driven population differences**

Gene expression and alternative splicing differences between human populations are under **genetic control**

Gene expression and alternative splicing differences between human populations are under **genetic control**

Ribosomal proteins are differentially spliced between populations across tissues

Ribosomal proteins are differentially spliced between populations across tissues

Ribosomal proteins are differentially spliced between populations across tissues

translating ribosome

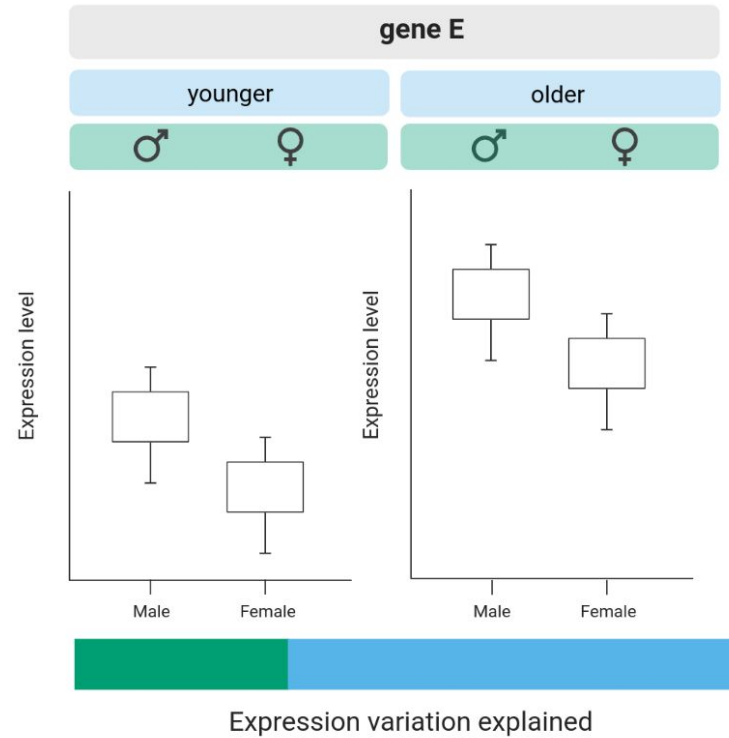

Ribosomal proteins are differentially spliced between populations across tissues

Lack of **multi-tissue** and **multi-trait** transcriptomic studies

- Transcriptomic studies limited to one or few tissues
- Transcriptomic studies limited to a **single trait**
- Transcriptomic studies limited to gene expression or alternative splicing

Multiple traits have **additive effects** on gene expression levels

Multiple traits have **additive effects** on gene expression levels

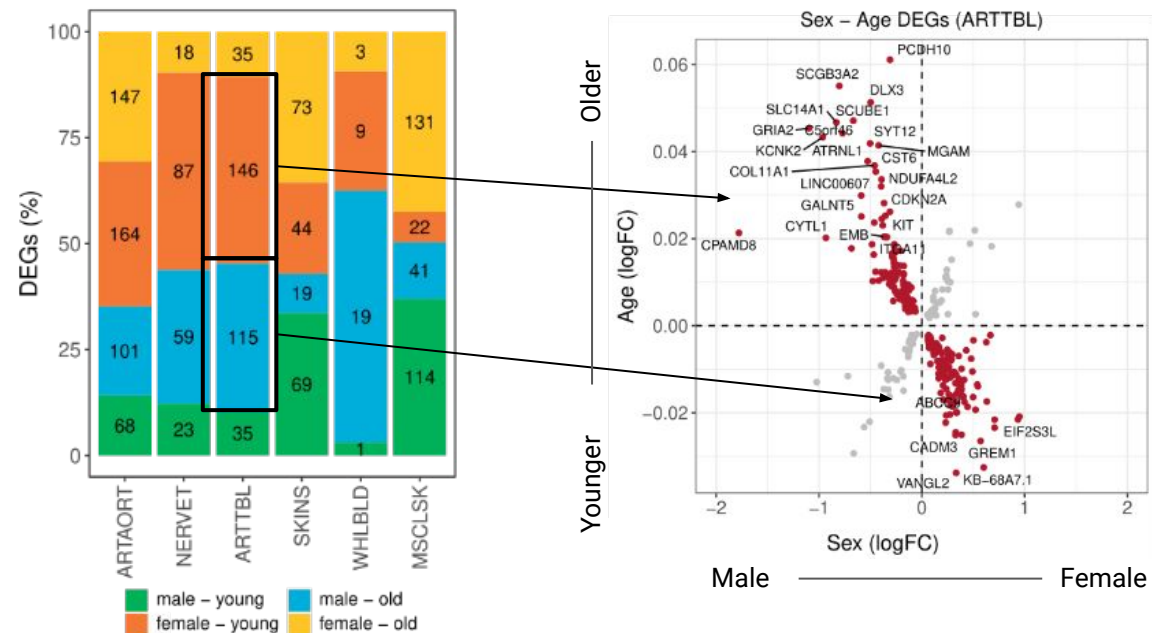

Additive effects have biased directionalities

Additive effects have biased directionalities

Additive effects have biased directionalities

Additive effects and precision medicine

Additive effects and precision medicine

The landscape of expression and alternative splicing variation across human traits (under review)

histology images

46 tissues
781 individuals

22,967 genes
62,269 splicing events

Demographic traits

Clinical traits

The **tibial nerve** is the tissue most affected by type 1 and 2 diabetes

The **tibial nerve** is the tissue most affected by type 1 and 2 diabetes

The **tibial nerve** is the tissue most affected by type 1 and 2 **diabetes**

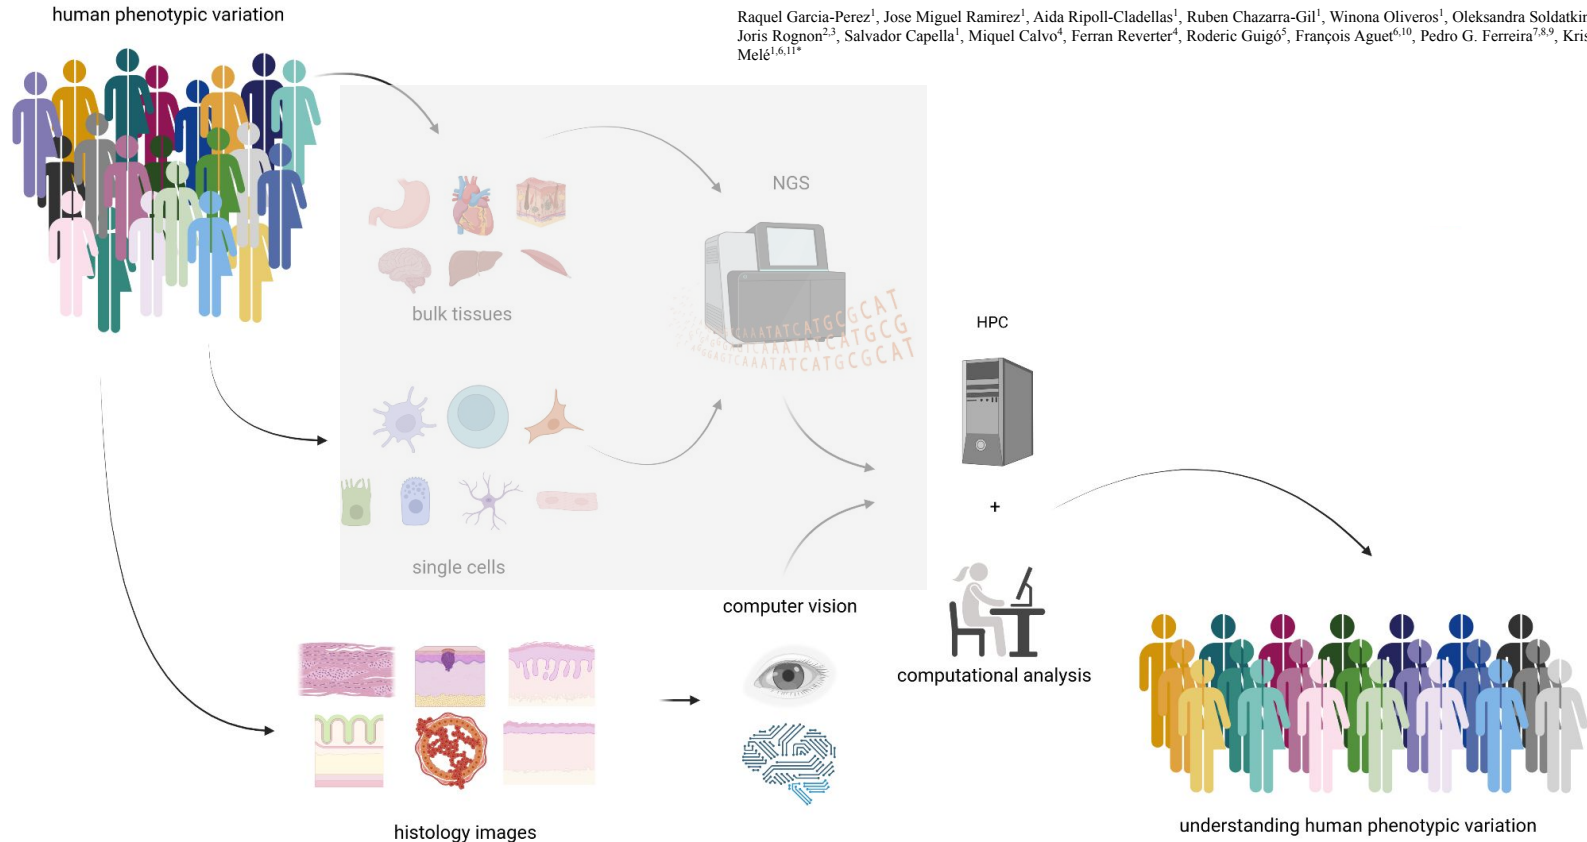

Diabetic neuropathy

- numbness or reduced ability to feel pain or temperature changes
- tingling or burning feeling
- sharp pains or cramps
- muscle weakness
- extreme sensitivity to touch
- serious foot problems, such as ulcers, infections, and bone and joint damage

The landscape of expression and alternative splicing variation across human traits (under review)

Raquel Garcia-Perez¹, Jose Miguel Ramirez¹, Aida Ripoll-Cladellas¹, Ruben Chazarra-Gil¹, Winona Oliveros¹, Oleksandra Soldatkina¹, Mattia Bosio¹, Paul Joris Rognon^{2,3}, Salvador Capella¹, Miquel Calvo⁴, Ferran Reverter⁴, Roderic Guigó⁵, François Aguet^{6,10}, Pedro G. Computer vision techniques allow us to **predict diabetic status**

Histology images

non-diabetic

diabetic

Support vector machine

- training set (75% of the data)
- test set (25% of the data)
- 100 permutations

Computer vision techniques allow us to **predict diabetic status**

Histology images

Support vector machine

- training set (75% of the data)
- test set (25% of the data)
- 100 permutations

We identify genes associated with **diabetic neuropathy**

Take home messages

- Ancestry, sex, age and BMI simultaneously influence gene expression variation but their relative importance is tissue-specific.
- Alternative splicing variation is mostly driven by differences between populations.
- Transcriptome differences between human populations are mostly *cis*-driven.
- Ribosomal proteins are differentially spliced between human populations.
- Additive effects are widespread and tissue-specific
- The tissue most affected by type 1 and 2 diabetes is the tibial nerve.
- Machine learning analysis of tibial nerve histology images allows us to predict the diabetic status and to find genes associated with diabetic neuropathy.
